## 1 Two user commands

- For $n>0$, expanding $\backslash$ MultiExpand $\{n\} \backslash$ macro twice gives the $n$-th expansion of \macro.
- For $n>0$, expanding $\backslash$ MultiExpandAfter $\{n\} \backslash$ macroA $\backslash$ macroB twice expands \macroB $n$ times before expanding \macroA.

Note that neither functions work for $n=0$.
These can typically be combined as
\MultiExpand\{7\}\%

[^0]```
\MultiExpandAfter{4}\a\MultiExpandAfter{7}\b%
\MultiExpandAfter{3}\c\d
```

which would expand $\backslash \mathrm{d} 3$ times, then $\backslash \mathrm{c} 5$ times (2 of the 7 times were used to expand $\backslash$ MultiExpandAfter $\{3\}$ ), then $\backslash \mathrm{b}$ twice ( $4-2$ ), and finally $\backslash \mathrm{a}$ five times $(7-2)$. Note that all this happens in precisely two steps of expansion.

In some cases, one needs to achieve the same effect in one step only. For this, we use the first expansion of \MultiExpand, which is \romannumeral \multiexpand, or of \MultiExpandAfter, which is $\backslash r o m a n n u m e r a l ~ \ m u l t i e x p a n d a f t e r)$. Expanding \romannumeral $\backslash m u l t i e x p a n d\{n\}$ once expands the following token $n$ times, and similarly for $\backslash$ romannumeral $\backslash m u l t i e x p a n d a f t e r\{n\}$.

These are especially useful when we want to expand several times a very specific token which is buried behind many others. Example: expanding the following code twice,

```
\MultiExpand{3}\expandafter\macroA\expandafter\macroB%
\romannumeral\multiexpandafter{4}\macroC\macroD
```

will expand $\backslash$ macroD 4 times, then will expand $\backslash$ macroA $2=3-1$ additional times.

Note: as we mentionned, this breaks for $n=0$. But in this case, consider using \expandafter $\backslash e m p t y$, or a variant thereof.

## 2 How it works

The primitive \romannumeral expands what follows fully until it builds a full number. It will remove exactly one trailing space if the first non-digit token is a space. So if we expand the construction \romannumeral0\expandafter $\backslash$ space once, then \romannumeral will see the 0, and expand \expandafter: it cannot yet be sure that it won't find another digit afterwards. This expands the next token once. In other words, \romannumeral0\expandafter $\backslash$ space behaves as if it was not there.

This is how we end our loop. Namely, \multiexpand $\{\langle n\rangle\}$ checks if $n<2$, in which case it stops with $0 \backslash$ expandafter $\backslash$ space. If $n \geq 2$, then it simply expands to $\backslash m u l t i e x p a n d\{\langle n-1\rangle\}$, plus the relevant $\backslash$ expandafters meant to expand the next token once. ${ }^{1}$
